Credentials in **blockchain**

CowStamp

my certificate, my proof

CowStamp.com

ASSESSORS

CowStamp

The platform that allows to manage verifiable digital credentials using the most advanced standards with **Blockchain** registration.

my certificate, my proof

Digital credentials, let's focus

To understand and explain what is a **digital credential**, before we need to define some key concepts.

¿What is a digitally verifiable credential?

Digitally verifiable credential

It is a digital document with a defined structure called **badge**, that allows an issuer to certify some given information about a recipient.

Digital credentials registered on the *blockchain* allows to prove the recipient they acquired some knowledge or some other fact to certify

Issuer **Credential** **Recipient**

Some Basic concepts

Basic concepts

Certificate

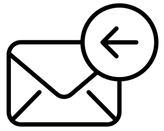
File issued by a trusted entity providing some information about a digital identity

Badge

Data structure containing information, fact or achievement being acknowledged

Issuer

Entity who creates the credential



Recipient

Also called subject, is the person or entity the badge is being awarded to.

The origin of credentials

Mozilla Foundation & IMS Global suggested a digital credential issuing protocol creating an open-source international standard called Open Badges, in the late 90s.

The *blockchain* technology changes everything. It provide new tools so the old standards need to adapt so they can offer a new range of features towards data sovereignty,

Everything changes with blockchain

Credentials on the *blockchain*

The disruption of the *blockchain* technology forces to adapt the actual standards for their inclusion. This is why **MIT Media Lab** extends the implementation of the **Open Badges** standard with a new standard called **Blockcerts.** This standard allows the registration of digital credentials using *blockchain* technologies with the necessary information to be verified.

The use of the **Blockcerts** standard introduces the need to transact on a *blockchain* to register a proof of the digitalized documents and so, take advantage of the *Blockchain* capabilities: **digital signature, timestamp, information distribution and data immutability.**

Certificate Oriented Web

Credentials on the *blockchain*

Nonetheless, the **Blockcerts** standard v2.1 does not define the management of the issuer identity, being an incomplete system, one can not validate the identity of the issuer. So, this credentials can not be legally binding per se.

To go through this limitation, **BTC Assessors** proposes a new standard, **Cowcerts**, allowing the management of the issuer's identity, raising the usability of digital credentials making possible for them to have legal validity.

CowStamp platform is based on the **Cowcerts** standard, being compatible with all the mentioned standards.

Blockchain: the revolution of certification

Blockchain technologies revolutionized the **verified digital credentials** business, making it possible to validate the authenticity and the date of issuance without a trusted third party in a decentralized registry

¿What brings the certification in blockchain?

Introduction

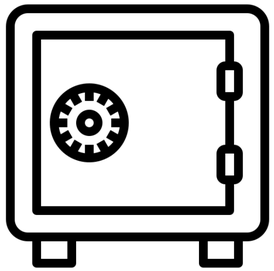
Digital Signature

The **digital signature** is a key aspect on the credential certification in ***blockchain***.

Every time we register a proof on the *blockchain* we need to digitally sign it. This is why every proof goes related to the issuer digital signature.

¿What brings the certification in blockchain?

Introduction



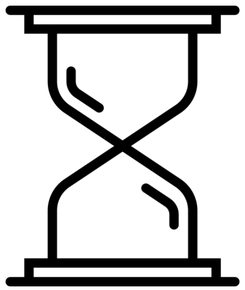
Immutability

One of the most important characteristics of well-designed and implemented *blockchains* is the **immutability of the registers** included in their *blocks*.

Being able to register a digital credential proof on the *blockchain*, guarantees us that the registered proof has not been corrupted over time.

¿What brings the certification in blockchain?

Introduction



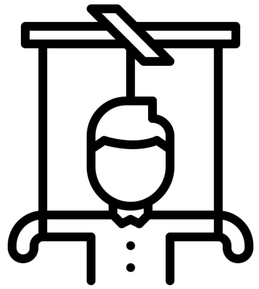
Timestamp

One of the main features of the *blockchain* is the **timestamp** included in each block.

The ***timestamp*** allows to validate in which moment was **registered a digital credential**, avoiding possible frauds or forgeries on the issuing date. And as the *blockchain* is decentralized, the timestamp too and therefore we don't rely on a centralized timestamp authority (TSA).

¿What brings the certification in *blockchain*?

Introduction



Sovereignty

Blockchain technology allows us to build an ecosystem where each and every user has **control of his information**, making it possible to share only the information that matters in every case, in a format that can be verified without showing unnecessary sensitive data.

In this way, credentials contain only the necessary **information to be verified**, protecting the user identity and avoiding abusive control from third parties of the users' data.

Digitally verifiable credentials are the future of certification, and the future is **now**!

¿How can I manage my verifiable credentials?

CowStamp

¿What is CowStamp?

CowStamp

The digital credentials management platform that allows to create issue and receive verifiable credentials registered on the ***blockchain,*** compatible with **Blockcerts** and following the **Cowcerts** standard.

¿what offers CowStamp?

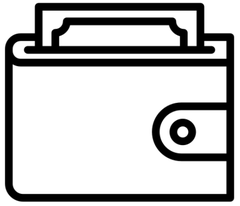
Características

Digital identity verification

Allows to verify credentials issuers and recipient identity through social media and/or the digital certificate issued by a country or accredited entity (X.509).

¿Que ofrece CowStamp?

Características



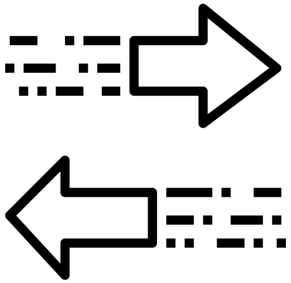
Usable in multiple wallets

CowStamp integrates with the the most popular **wallets*, making it possible to handle** the cryptographic keys in the safest possible way without forgetting the usability of the platform. We can then register into **multiple *blockchains the* wallet of our choice**.

Currently the only published integration is with the **MetaMask wallet*

¿Que ofrece CowStamp?

Características

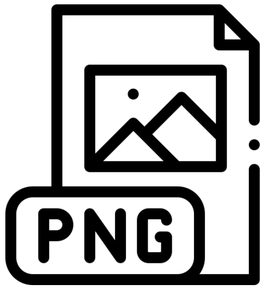


Issuance and reception of credentials

It is easy to issue and receive **credentials**, through a user-friendly entourage allowing to see, manage and validate verifiable credentials on the simplest and fastest way

¿Que ofrece CowStamp?

Características



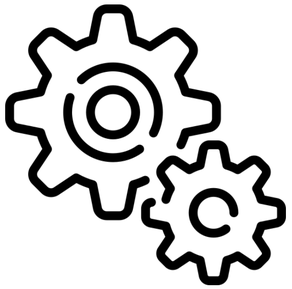
Understandable credentials format

The issuing of digital credentials, with **CowStamp** is done in a **comprehensive format** for all the devices thanks to the use of **PNG*** open format file.

**Work in progress, not yet published*

¿Qué ofrece CowStamp?

Características



Accepting multiple schemes

The implementation of **multiples badge *schemes*** on the **Cowcerts** standard makes possible to create and verify more complex credentials, as a new feature in the sector.

Because custom use cases will require custom verification needs, we provide schemes so every user can choose their own custom verification steps.

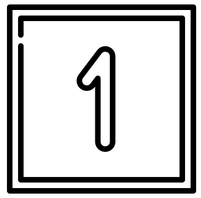
¿How to issue a credential with CowStamp?

The issuing of a verifiable digital credential with **CowStamp** is **highly simplified.**

By just signing up in the platform and following 5 simple steps, we can start issuing our credentials.

¿Who is issuing?

Credentials in 5 steps



Create an issuer of the credential

We first need to define **who is going to issue** the credentials, being an institution or an individual, we create with **CowStamp** an **issuer of credentials**.

¿Is the issuer verified?

Credenciales en 5 pasos

Verify the identity of the issuer

To be able to give legal validity to the credential, is mandatory to generate **proof of identity** of the issuer.

In this goal, **CowStamp** allows to establish a relation between the digital identity of the issuer on the *blockchain* with their profiles in **social media, DID** or with other **digital certificates** issued by trusted institutions.

¿What information is being certified?

Credenciales en 5 pasos

Define a badge’s information

The credential creation process involves specifying the **content of the badge being awarded**. Therefore we must need the achievement or fact the credential certifies.

¿Quién es el receptor?

Credenciales en 5 pasos

Assign a credential recipient

To issue a credential, we need to **assign the badge a recipient or subject**. To do that, the issuer will have to introduce the data they want to identify the recipient with.

Registramos la prueba

Credenciales en 5 pasos

Register the credential in the blockchain

Registering the credential in the *blockchain* will **register an immutable proof of the integrity and authentication of the credential** by storing digital signatures with a timestamp for its posterior verification.

I have my verifiable credential, ¿now what?

When some issues us a verifiable credential, **we can download in the platform a digital file in JSON format** that can be shared and verified easily as any file.

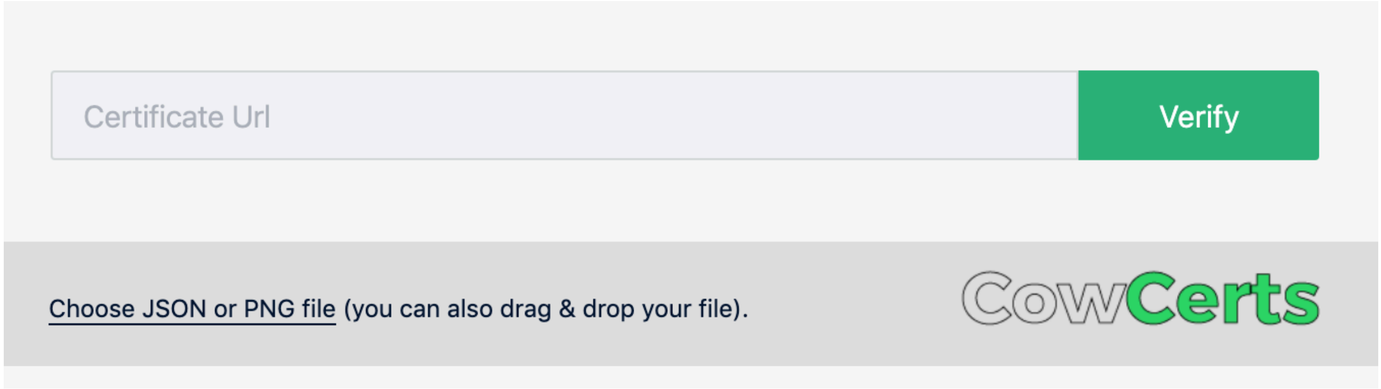
¿Cómo se valida?

Validador

Verify my credential

To embrace all digital credential features, it's basic to be able to share them with whoever we want and that they can **verify it independently without requiring a third party, neither the issuer or the credential recipient**.

Cowcerts provides an **open source, enterprise grade digital credentials verifier** implemented in Javascript that cares about identity and trust.



CowStamp's roadmap

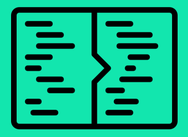
IPFS storage support

Semi-custodial wallet service

Embedded JSON in a PNG

Badges store

Fully implement and support DIDs



Badge schemes
